

AutoML Modeling Report

Jorge Luiz Figueira da Silva Junior

Binary Classifier with Clean/Balanced Data

Train/Test Split

How much data was used for training? How much data was used for testing?

A total of 200 instances were used as a dataset. The split into training, testing, and validation sets is given in the chart below.

Labels	Images	Train	Validation	Test
normal		80	10	10
pneumonia		80	10	10

Confusion Matrix

What do each of the cells in the confusion matrix describe? What values did you observe (include a screenshot)? What is the true positive rate for the "pneumonia" class? What is the false positive rate for the "normal" class?

The Confusion Matrix provides an effective measure of the classification model by showing the number of correct classifications (True Positives, True Negatives) versus incorrect classifications (False Positive, False Negative).

True positives are the correct classification of pneumonia, which is 97%. False Positives are cases in which the true label is negative ("normal" class) however the model classified it as positive ("pneumonia" class). As noted in the confusion matrix, not occurred these cases, so the rate is not specified.

False Negatives are cases in which the true label is positive ("pneumonia") however classified as negative ("normal"). The False Negative rate in this model is 3%. Finally, True Negatives are the cases where the true label is negative ("normal") and the predicted label is classified as negative. The True Negative rate is 100%.

True Label	Predicted Label	
	pneumonia	normal
pneumonia	97%	3%
normal	-	100%

Precision and Recall

What does precision measure?
What does recall measure? What
precision and recall did the model
achieve (report the values for a
score threshold of 0.5)?

Precision measures the ratio of true positives to the predicted values. Recall measures the ratio of true positives to actual positives.

Precision ?	95%
Recall ?	95%

Score Threshold

When you increase the threshold
what happens to precision? What
happens to recall? Why?

A higher threshold results in an increase in precision (because the model never makes a prediction unless it is extremely sure) but the recall (the percentage of positive examples that the model gets right) decreases.

* Using a score threshold of 0.7

Precision ?	100%
Recall ?	90%

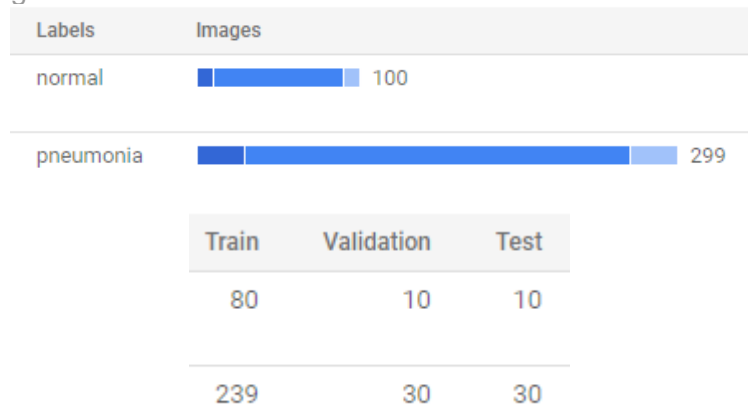

Binary Classifier with Clean/Unbalanced Data

Train/Test Split

How much data was used for training? How much data was used for testing?

The split into training, testing, and validation sets is given in the chart below.

Confusion Matrix

How has the confusion matrix been affected by the unbalanced data? Include a screenshot of the new confusion matrix.

Regarding the clean/balanced model, there was a significant increase in the True Positive rate (correct classifications of "Pneumonia") and a drop in the True Negative rate (correct classifications of "normal").

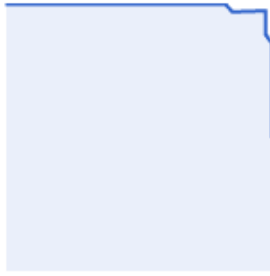

This is because a bias was introduced in the model. As there are more images of the "pneumonia" class, therefore, the model will learn more patterns from this class, and the effect of this is the one visualized in the confusion matrix, a tendency to predict the class with more images.

True Label	Predicted Label	
	pneumonia	normal
pneumonia	100%	-
normal	10%	90%

Precision and Recall

How have the model's precision and recall been affected by the unbalanced data (report the values for a score threshold of 0.5)?

There was a slight improvement in precision and model recall.

	<p>unbalanced_163353_20211006021646</p>  <p>Average precision ? 0.993</p> <p>Precision* ? 97.5%</p> <p>Recall* ? 97.5%</p> <p>* Using a score threshold of 0.5</p>
<p>Unbalanced Classes From what you have observed, how do unbalanced classes affect a machine learning model?</p>	<p>Balancing the data is as important if not more to produce an unbiased model. As the results suggest, there is a tendency for the model to classify the examples as pneumonia.</p>

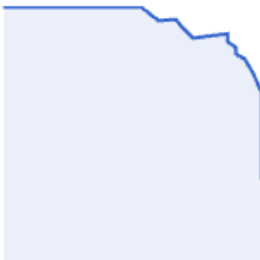

Binary Classifier with Dirty/Balanced Data

<h3>Confusion Matrix</h3> <p>How has the confusion matrix been affected by the dirty data? Include a screenshot of the new confusion matrix.</p>	<p>The model obtained in these configurations had a drastic drop in performance.</p> <table><tr><th rowspan="2">True Label</th><th colspan="2">Predicted Label</th></tr><tr><th>pneumonia</th><th>normal</th></tr><tr><th>pneumonia</th><td>50%</td><td>50%</td></tr><tr><th>normal</th><td>30%</td><td>70%</td></tr></table>	True Label	Predicted Label		pneumonia	normal	pneumonia	50%	50%	normal	30%	70%
True Label	Predicted Label											
	pneumonia	normal										
pneumonia	50%	50%										
normal	30%	70%										
<h3>Precision and Recall</h3> <p>How have the model's precision and recall been affected by the dirty data (report the values for a score threshold of 0.5)? Of the binary classifiers, which has the highest precision? Which has the highest recall?</p>	<p>This model, when compared to the model with balanced data and even with the model with unbalanced data, had the worst performance with 60% of precision and recall.</p>											

	<p>dirty_balanced_20211005080153</p>  <p>Average precision ? 0.558</p> <p>Precision* ? 60%</p> <p>Recall* ? 60%</p> <p>* Using a score threshold of 0.5</p> <p>For this experiment, the Binary Classifier with Clean/Unbalanced Data had the highest precision and recall.</p>
<p>Dirty Data From what you have observed, how does dirty data affect a machine learning model?</p>	<p>One of the most common issues with training data is using mislabeled data. Models learn from patterns extracted from training data. As equal patterns are seen on both labels, the model had difficulties in data separability, resulting in performance poorly.</p>

3-Class Model

<p>Confusion Matrix Summarize the 3-class confusion matrix. Which classes is the model most likely to confuse? Which class(es) is the model most likely to get right? Why might you do to try to remedy the model's "confusion"? Include a screenshot of the new confusion matrix.</p>	<p>From the confusion matrix it is observed that the model makes confusion between the "viral" and "bacterial" classes. Still, the model was able to predict all instances of the "viral" class. The model also got all the correct predictions of the normal "class".</p> <p>According to the literature, the classification of subcategories is still quite challenging. In this sense, for this model I would unify the labels "viral" and "bacterial" as being solely "pneumonia".</p>
